Agenda

- 1. Analyzing nested loops.
- 2. What is Θ notation, really?

DSC 40B Theoretical Foundations II

Lecture 2 | Part 2

Nested Loops

Example 1: Interview Problem

Example 1: Interview Problem

- Design an algorithm to solve the following problem...
- Given the heights of n people, what is the height of the tallest doctor you can make by stacking two of them?

Exercise

- What is the time complexity of the brute force solution?
 - **Bonus:** what is the **best possible** time complexity of any solution?

The Brute Force Solution

- Loop through all possible (ordered) pairs.
 - How many are there?
- Check height of each.
- Keep the best.

Time/exec. # of execs.

```
def tallest doctor(heights):
   max height = -float('inf')
   n = len(heights)
   for i in range(n):
       for j in range(n):
           if i == i:
               continue
           height = heights[i] + heights[j]
           if height > max_height:
              max height = height
   return max height
```

Time Complexity

- ▶ Time complexity of this is $\Theta(n^2)$.
- ► **TODO**: Can we do better?
- Note: this algorithm considers each pair of people **twice**.
- We'll fix that in a moment.

First: A shortcut

- Making a table is getting tedious.
- Usually we'll find a line that **dominates** time complexity; i.e., yields the leading term of T(n).

Totalling Up

```
for i in range(n):
    for j in range(n):
        height = heights[i] + heights[j]
  ▶ On outer iter. # 1, inner body runs times.
  ▶ On outer iter. # 2, inner body runs times.
  \triangleright On outer iter. # \alpha, inner body runs times.
  The outer loop body runs times.
```

```
def f(n):
    for i in range(3*n**3 + 5*n**2 - 100):
        for j in range(n**5, n**6):
            print(i, j)
```

Example 2: The Median

- ► **Given:** real numbers $x_1, ..., x_n$.
- ► Compute: *h* minimizing the total absolute loss

$$R(h) = \sum_{i=1}^{n} |x_i - h|$$

Example 2: The Median

► **Solution**: the **median**.

- ► That is, a **middle** number.
- ▶ But how do we actually **compute** a median?

A Strategy

- **Recall**: one of $x_1, ..., x_n$ must be a median.
- ▶ **Idea**: compute $R(x_1)$, $R(x_2)$, ..., $R(x_n)$, return x_i that gives the smallest result.

$$R(h) = \sum_{i=1}^{n} |x_i - h|$$

Basically a brute force approach.

Exercise

- What is the time complexity of this brute force approach?
- How long will it take to run on an input of size 10,000?

```
def median(numbers):
    min h = None
    min value = float('inf')
    for h in numbers:
        total_abs_loss = 0
        for x in numbers:
            total abs loss += abs(x - h)
        if total abs loss < min value:</pre>
            min value = total abs loss
            min h = h
    return min h
```

The Median

The brute force approach has $\Theta(n^2)$ time complexity.

TODO: Is there a better algorithm?

The Median

- The brute force approach has $\Theta(n^2)$ time complexity.
- ► **TODO**: Is there a better algorithm?
 - ► It turns out, you can find the median in *linear* time.¹

¹Well, expected time.

```
In [8]: numbers = list(range(10_000))
In [9]: %time median(numbers)
CPU times: user 7.26 s, sys: 0 ns, total: 7.26 s
Wall time: 7.26 s
```

CPU times: user 4.3 ms, sys: 2 µs, total: 4.3 ms

In [10]: %time mystery median(numbers)

Wall time: 4.3 ms

Careful!

Not every nested loop has $\Theta(n^2)$ time complexity!

```
def foo(n):
    for x in range(n):
        for y in range(10):
            print(x + y)
```

DSC 40B Theoretical Foundations II

Lecture 2 | Part 3

Dependent Nested Loops

Example 3: Tallest Doctor, Again

Our previous algorithm for the tallest doctor computed height for each *ordered* pair of people.

```
\triangleright i = 3 and j = 7 is the same as i = 7 and j = 3
```

▶ **Idea**: consider each *unordered* pair only once:

```
for i in range(n):
    for j in range(i + 1, n):
```

What is the time complexity?

Pictorially

```
for i in range(4):
    for j in range(4):
         print(i, j)
(0.0) (0.1) (0.2) (0.3)
(1,0) (1,1) (1,2) (1,3)
(2,0) (2,1) (2,2) (2,3)
(3,0) (3,1) (3,2) (3.3)
```

Pictorially

```
for i in range(4):
    for j in range(i + 1, 4):
        print(i, j)

(0,1) (0,2) (0,3)
        (1,2) (1,3)
```

```
def tallest_doctor_2(heights):
    max_height = -float('inf')
    n = len(heights)
    for i in range(n):
        for j in range(i + 1, n):
             height = heights[i] + height[j]
             if height > max_height:
             max height = height
```

- ► **Goal**: How many times does line 6 run in total?
- Now inner nested loop **depends** on outer nested loop.

Independent

```
for i in range(n):
    for j in range(n):
    ...
```

- Inner loop doesn't depend on outer loop iteration #.
- ► Just multiply: inner body executed *n*² times.

Dependent

```
for i in range(n):
    for j in range(i, n):
    ...
```

- Inner loop depends on outer loop iteration #.
- Can't just multiply: inner body executed ??? times.

Dependent Nested Loops

```
for i in range(n):
    for j in range(i + 1, n):
        height = heights[i] + heights[j]
```

Idea: find formula $f(\alpha)$ for "number of iterations of inner loop during outer iteration α^{2} "

Then total: $\sum_{n=1}^{n} f(\alpha)$

 $^{^{2}}$ Why α and not i? Python starts counting at 0, math starts at 1. Using i would be confusing – does it start at 0 or 1?

```
for i in range(n):
    for j in range(i + 1, n):
        height = heights[i] + heights[j]
```

- ▶ On outer iter. # 1, inner body runs _____ times.
- ► On outer iter. # 2, inner body runs _____ times.
- \triangleright On outer iter. # α , inner body runs _____ times.
- ► The outer loop body runs _____ times.

Totalling Up

- \triangleright On outer iteration α , inner body runs $n \alpha$ times.
 - ► That is, $f(\alpha) = n \alpha$
- ► There are *n* outer iterations.
- So we need to calculate:

$$\sum_{\alpha=1}^{n} f(\alpha) = \sum_{\alpha=1}^{n} (n - \alpha)$$

$$(n-1) + (n-2) + ... + (n-\alpha) + (n-(n-1)) + (n-n)$$
1st outer iter 2nd outer iter 2nd outer iter = (n-1)th outer iter nth outer iter =

1 + 2 + 3 + ... + (n - 3) + (n - 2) + (n - 1)

Aside: Arithmetic Sums

- ► 1 + 2 + 3 + ...+ (n-1) + n is an arithmetic sum.
- Formula for total: n(n + 1)/2.
- You should memorize it!

Time Complexity

- ► tallest_doctor_2 has $\Theta(n^2)$ time complexity
- Same as original tallest_doctor!
- Should we have been able to guess this? Why?

Reason 1: Number of Pairs

- We're doing constant work for each unordered pair.
- \triangleright Recall from 40A: number of pairs of n objects is

$$\binom{n}{2} = \frac{n!}{2!(n-2)!} = \frac{n(n-1)}{2}$$

► So $\Theta(n^2)$

Reason 2: Half as much work

- Our new solution does roughly half as much work as the old one.
- But Θ doesn't care about constants: $\frac{1}{2}\Theta(n^2)$ is still Θ(n^2).

Main Idea

If the loops are dependent, you'll usually need to write down a summation, evaluate.

Main Idea

Halving the work (or thirding, quartering, etc.) doesn't change the time complexity.

Exercise

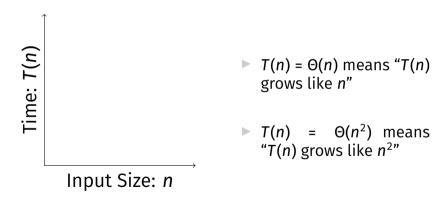

Design a linear time algorithm for this problem.

DSC 40B Theoretical Foundations II

Lecture 2 | Part 4

Growth Rates

Linear vs. Quadratic Scaling

Definition

An algorithm is said to run in linear time if $T(n) = \Theta(n)$.

Definition

An algorithm is said to run in quadratic time if $T(n) = \Theta(n^2)$.

Linear Growth

- ► If input size doubles, time roughly doubles.
- ▶ If code takes 5 seconds on 1,000 points...
- ...on 100,000 data points it takes ≈ 500 seconds.
- ▶ i.e., 8.3 minutes

Quadratic Growth

- If input size doubles, time roughly quadruples.
- ▶ If code takes 5 seconds on 1,000 points...
- ...on 100,000 points it takes ≈ 50,000 seconds.
- i.e., ≈ 14 hours

In data science...

- Let's say we have a training set of 10,000 points.
- If model takes **quadratic** time to train, should expect to wait minutes to hours.
- If model takes **linear** time to train, should expect to wait seconds to minutes.
- These are rules of thumb only.

Exponential Growth

- Increasing input size by one *doubles* (triples, etc.) time taken.
- Grows very quickly!
- **Example:** brute force search of 2ⁿ subsets.

```
for subset in all_subsets(things):
    print(subset)
```

Logarithmic Growth

- To increase time taken by one unit, must double (triple, etc.) the input size.
- Grows very slowly!
- ▶ $\log n$ grows slower than n^{α} for any $\alpha > 0$
 - I.e., $\log n$ grows slower than $n, \sqrt{n}, n^{1/1,000}$, etc.

Exercise

What is the asymptotic time complexity of the code below as a function of n?

```
1 = 1
while i <= n</pre>
```

Solution

Same general strategy as before: "how many times does loop body run?"

```
# iters.
while i <= n
    i = i * 2
                                5
                                6
                                8
```

Common Growth Rates

- ▶ Θ(1): constant
- \triangleright $\Theta(\log n)$: **logarithmic**
- **▶** Θ(*n*): linear
- \triangleright $\Theta(n \log n)$: linearithmic
- \triangleright $\Theta(n^2)$: quadratic
- \triangleright $\Theta(n^3)$: cubic
- \triangleright $\Theta(2^n)$: **exponential**

Exercise

Which grows faster, n! or 2^n ?

DSC 40B Theoretical Foundation II

Lecture 2 | Part 5

Big Theta, Formalized

So Far

- Time Complexity Analysis: a picture of how an algorithm scales.
- Can use Θ-notation to express time complexity.
- Allows us to **ignore** details in a rigorous way.
 - Saves us work!
 - But what exactly can we ignore?

Now

- ► A deeper look at **asymptotic notation**:
- ► What does Θ(·) mean, exactly?
- ► Related notations: $O(\cdot)$ and $Ω(\cdot)$.
- How these notations save us work.

Theta Notation, Informally

 \triangleright $\Theta(\cdot)$ forgets constant factors, lower-order terms.

$$5n^3 + 3n^2 + 42 = \Theta(n^3)$$

Theta Notation, Informally

 $ightharpoonup f(n) = \Theta(g(n))$ if f(n) "grows like" g(n).

 $5n^3 + 3n^2 + 42 = \Theta(n^3)$

Theta Notation Examples

$$\triangleright$$
 4n² + 3n - 20 = $\Theta(n^2)$

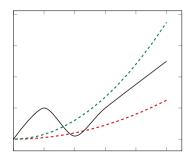

$$ightharpoonup 3n + \sin(4\pi n) = \Theta(n)$$

$$\triangleright 2^n + 100n = \Theta(2^n)$$

Definition

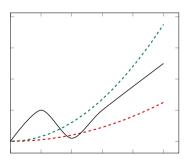

We write $f(n) = \Theta(g(n))$ if there are positive constants N, c_1 and c_2 such that for all $n \ge N$:

$$c_1 \cdot g(n) \le f(n) \le c_2 \cdot g(n)$$

Main Idea

If $f(n) = \Theta(g(n))$, then when n is large f is "sandwiched" between copies of g.

Proving Big-Theta

We can prove that $f(n) = \Theta(g(n))$ by finding these constants.

$$c_1g(n) \le f(n) \le c_2g(n)$$
 $(n \ge N)$

Requires an upper bound and a lower bound.

Strategy: Chains of Inequalities

► To show $f(n) \le c_2 g(n)$, we show:

$$f(n) \le \text{(something)} \le \text{(another thing)} \le \dots \le c_2 g(n)$$

- At each step:
 - We can do anything to make value larger.
 - ▶ But the goal is to simplify it to look like g(n).

- ► Show that $4n^3 5n^2 + 50 = \Theta(n^3)$.
- Find constants c_1, c_2, N such that for all n > N:

$$c_1 n^3 \le 4n^3 - 5n^2 + 50 \le c_2 n^3$$

They don't have to be the "best" constants! Many solutions!

$$c_1 n^3 \le 4n^3 - 5n^2 + 50 \le c_2 n^3$$

- We want to make $4n^2 5n^2 + 50$ "look like" cn^3 .
- For the upper bound, can do anything that makes the function **larger**.
- For the lower bound, can do anything that makes the function **smaller**.

$$c_1 n^3 \le 4n^3 - 5n^2 + 50 \le c_2 n^3$$

Upper bound:

$$c_1 n^3 \le 4n^3 - 5n^2 + 50 \le c_2 n^3$$

Lower bound:

Upper-Bounding Tips

"Promote" lower-order positive terms:

$$3n^3 + 5n \le 3n^3 + 5n^3$$

"Drop" negative terms

$$3n^3 - 5n \le 3n^3$$

Lower-Bounding Tips

► "Drop" lower-order **positive** terms:

$$3n^3 + 5n \ge 3n^3$$

"Promote and cancel" negative lower-order terms if possible:

$$4n^3 - 2n \ge 4n^3 - 2n^3 = 2n^3$$

Lower-Bounding Tips

"Cancel" negative lower-order terms with big constants by "breaking off" a piece of high term.

$$4n^{3} - 10n^{2} = (3n^{3} + n^{3}) - 10n^{2}$$

$$= 3n^{3} + (n^{3} - 10n^{2})$$

$$n^{3} - 10n^{2} \ge 0 \text{ when } n^{3} \ge 10n^{2} \implies n \ge 10:$$

$$\ge 3n^{3} + 0 \qquad (n \ge 10)$$

Caution

- ► To upper bound a fraction A/B, you must:
 - Upper bound the numerator, A.
 - Lower bound the denominator, B.

- And to lower bound a fraction A/B, you must:
 - Lower bound the numerator, A.
 - Upper bound the denominator, B.

Exercise

Let $f(n) = [3n + (n \sin(\pi n) + 3)]n$. Which of the following are true?

$$f = \Theta(n)$$

$$ightharpoonup f = \Theta(n^2)$$

$$ightharpoonup f = Θ(n sin(\pi n))$$

$$f = \Theta(n^2(n\sin(\pi n) + 3))$$
